Abstract—Simple yet useful analytical formulas for delay, slope and crosstalk noise amplitude for capacitively coupled two-, three- and infinite-line systems are derived assuming bus lines and other signal lines in deep-submicron VLSI's. The calculated results using the derived formulas are extensively compared with SPICE simulation results to demonstrate the validity of the analytical expressions. Two modes have been studied; the case where adjacent lines are driven from the opposite direction and the case where adjacent lines are driven from the same direction. These cases corresponds to the typical situations in VLSI designs and include worst cases in terms of noise amplitude and delay. Delay error in approximating the distributed RC lines by N-step r-ladder RC lumped circuit is also investigated.

1. Introduction

In deep submicron designs, interconnection related issues become more and more important in estimating timing behavior of VLSI's [1]. For instance, coupling capacitance is comparable to grounding capacitance. The coupling noise may cause malfunction and timing problem especially in dynamic circuits but even in static circuits, in addition, the noise may generate unexpected glitches which may give rise to timing and power problems.

Several attempts have been made to analytically treat the crosstalk in capacitively coupled interconnections. However, the results are limited to two-line systems and the case considered in the previous publications are limited to the case where adjacent lines are driven from the same direction. This paper extends the analysis and covers more general cases. The resultant formulas are more precise than the previously published expressions.

The delay of the RC distributed lines is also handled analytically in this paper. To the knowledge of the authors, formulas for the delay of the capacitively coupled distributed RC interconnection system have not been presented so rigorously and systematically as this paper. To analyze the capacitively coupled lines, moment matching technique based on Padé approximation is employed to give the analytical expressions.

The derived expressions are useful in estimating the noise and delay in the early stage of designs and give insight to coupling related issues.

2. Notations

Notations used in this paper are as follows.

c : capacitance of line per unit length.
C : total capacitance of line (=c.l).
c : coupling capacitance of line per unit length.
C C : total coupling capacitance of line (=c.c.l).
C t : equivalent capacitance of receiver MOSFET.

C T := C t /C.
d : pure delay of voltage waveform.
E i : step voltage of the driving point of line i (i = 1,2). The condition that E 1 =1, E 2 =1 is called an in-phase drive. The condition that E 1 =1, E 2 =-1 is called an out-phase drive. The condition that E 1 =1, E 2 =0 is called E 2 =0 drive.

K : residue corresponding to s 1.
l : line length.

m k : k-th moment of voltage waveform k (k=0,1).
n : number of adjacent lines (n=1 for two-line system, n=2 for three-line system and n=1 for infinite-line system).

n 1 :=n+1.
p :=1+(n+1)η.
R : total resistance of line per unit length.
R T :=R t /R.
R t : equivalent resistance of driver MOSFET.

R T :=R t /R.
s : Laplace variable.

t : time.

tp : time to give the noise peak.

tp : propagation delay using Padé approximation.

V i (x,t) : voltage of line i (i=1,2) in t domain.

V i (x,s) : voltage of line i (i=1,2) in s domain.

V p : peak noise voltage.

x : x-coordinate along the line.

η :=C L/C.

σ : minimum absolute pole.

τ : time constant in single exponential approximation.

3. Basic Equations

The basic equations which governs a capacitively coupled two-line system (Fig. 1) are written as follows.
where \( r_i \) and \( c_i \) are resistance and capacitance of line \( i \) (\( i=1,2 \)) per unit length. Since in bus structures and other wiring structures lines have the same resistance and capacitance per unit length, we assume \( r_i=r_2=r \) and \( c_i=c \).

When three-line system (Fig. 2) is considered, the following equations hold.

\[
\begin{align*}
\frac{\partial^2 v_1}{\partial x^2} &= r(c+2c) \frac{\partial v_1}{\partial t} - r c \frac{\partial v_2}{\partial t} \\
\frac{\partial^2 v_2}{\partial x^2} &= r(c+2c) \frac{\partial v_2}{\partial t} - r c \frac{\partial v_1}{\partial t} \\
\frac{\partial^2 v_3}{\partial x^2} &= r(c+2c) \frac{\partial v_3}{\partial t} - r c \frac{\partial v_4}{\partial t}
\end{align*}
\]

Fig. 2 Capacitively coupled three distributed RC lines.

On the other hand, if infinite lines are placed in parallel where the same boundary conditions are applied to every two lines as in Fig. 3, the following equations hold.

\[
\begin{align*}
\frac{\partial^2 v_1}{\partial x^2} &= r(c+2c) \frac{\partial v_1}{\partial t} - 2rc \frac{\partial v_2}{\partial t} \\
\frac{\partial^2 v_2}{\partial x^2} &= r(c+2c) \frac{\partial v_2}{\partial t} - 2rc \frac{\partial v_1}{\partial t} \\
\frac{\partial^2 v_3}{\partial x^2} &= r(c+2c) \frac{\partial v_3}{\partial t} - 2rc \frac{\partial v_4}{\partial t}
\end{align*}
\]

Fig. 3 Capacitively coupled infinite distributed RC lines.

All of the above-mentioned three equation sets (1), (2) and (3) can be represented by the following one set of equations.

\[
\begin{align*}
\frac{\partial^2 v_1}{\partial x^2} &= r(c+nc) \frac{\partial v_1}{\partial t} - nrc \frac{\partial v_2}{\partial t} \\
\frac{\partial^2 v_2}{\partial x^2} &= r(c+nc) \frac{\partial v_2}{\partial t} - nrc \frac{\partial v_1}{\partial t} \\
\frac{\partial^2 v_3}{\partial x^2} &= r(c+nc) \frac{\partial v_3}{\partial t} - nrc \frac{\partial v_4}{\partial t}
\end{align*}
\]

In the above equations (4), the following values should be set to \( n \) and \( c \) for each case.

Two-line case: \( n \rightarrow 1, \ c \rightarrow c \)

Three-line case: \( n \rightarrow 2, \ c \rightarrow c \)

Infinite-line case: \( n \rightarrow 1, \ c \rightarrow 2c \)

(4) can be simplified, if the following substitutions are made.

\[
\begin{align*}
v_1' &= (1+\eta)v_1 - n\eta v_2 \\
v_2' &= (1+\eta)v_2 - \eta v_1
\end{align*}
\]

are the resultant equations after the substitution. With a linear transformation, we have

\[
\begin{align*}
(v_1 + n v_2)' &= \dot{v}_1 + n \nu_2 \\
(v_1 - v_2)' &= (1 + (n + 1)\eta)(\dot{v}_1 - \dot{v}_2)
\end{align*}
\]

By Laplace transformation, the following equations can be derived.

\[
\begin{align*}
(V_1 + n V_2)' &= s(V_1 + n V_2) \\
(V_1 - V_2)' &= (1 + (n + 1)\eta)s(V_1 - V_2)
\end{align*}
\]

The solutions of the above equations are expressed as follows with the introduction of \( \gamma_1 \) and \( \gamma_2 \).

\[
\gamma_1 = \sqrt{s}, \quad \gamma_2 = \sqrt{(1 + (n + 1)\eta)s = \sqrt{ps}}
\]

\[
\begin{align*}
V_1 + n V_2 &= A'e^{\gamma_1 x} + B'e^{-\gamma_1 x} \\
V_1 - V_2 &= C'e^{\gamma_2 x} + D'e^{-\gamma_2 x}
\end{align*}
\]

, where \( A', B', C' \) and \( D' \) are integration constants.

\[
\begin{align*}
(n+1) V_1 &= A'e^{\gamma_1 x} + B'e^{-\gamma_1 x} + nC'e^{\gamma_2 x} + nD'e^{-\gamma_2 x} \\
(n+1) V_2 &= A'e^{\gamma_1 x} + B'e^{-\gamma_1 x} - C'e^{\gamma_2 x} - D'e^{-\gamma_2 x}
\end{align*}
\]

Then, the following are the general solutions to (4) in s-domain.

\[
\begin{align*}
V_1 &= A'e^{\gamma_1 x} + B'e^{-\gamma_1 x} + nC'e^{\gamma_2 x} + nD'e^{-\gamma_2 x} \\
V_2 &= A'e^{\gamma_1 x} + B'e^{-\gamma_1 x} - C'e^{\gamma_2 x} - D'e^{-\gamma_2 x}
\end{align*}
\]

A, B, C and D are to be obtained from boundary conditions.

A. Moment Matching Approach for Delay and Slope Calculation

Once A, B, C and D are obtained, closed-form expressions for \( V_1(x,s) \) and \( V_2(x,s) \) can be obtained using (5). Approximate voltage waveform of a full-swing line has a single exponential form with pure delay d shown in the following figure.
In order to obtain expressions for the delay \( t_{pd} \), the moment matching method (Pade approximation) is used [2-3], where the coefficients for \( s^0 \) and \( s^1 \) of the exact solution of (5) are matched to the coefficients of \( s^0 \) and \( s^1 \) of the approximate waveform in Fig. 4. The coefficient of \( s^0 \) is called the zero-th moment \( m_0 \), and the coefficient of \( s^1 \) is called the first moment \( m_1 \). Consequently, once the moments of (5) are obtained, the delay \( t_{pd} \) and the slope of the waveform can be calculated as follows using Pade approximation.

\[
\tau = \sqrt{2m_1 - m_0^2}, \quad d = m_0 \quad \text{and} \quad t_{pd} = d + d_1 = d + \tau \ln 2, \quad \text{slope}_{(s=0)} = \frac{1}{2\tau}
\]

In calculating the crosstalk noise, the moment matching approach is not effective because the noise shape varies from case to case and the assumption that the waveform is like Fig. 4 is not valid. For noise analysis, therefore, different approaches are taken from case to case.

4. Opposite Direction Drive

In this section, the mode where adjacent lines are driven from the opposite direction is handled. The situation is depicted in Fig. 5. For this mode, analytical expressions turn out to be very complicated if the equivalent resistance of driver MOSFET \( R_t \) and the equivalent capacitance of receiver MOSFET \( C_t \) are to be considered, that is, \( R_t \) and \( C_t \) are not equal to zero. The case of \( R_t = C_t = 0 \) is the worst case scenario in terms of the noise amplitude because the capacitance coupling effect is mitigated if \( R_t \) and \( C_t \) are finite. Consequently, the \( R_t = C_t = 0 \) case is treated here.

The boundary conditions for this case are as follows (Fig. 5).

\[
\begin{align*}
V_1(0,s) &= 0 \\
V_1(l,s) &= E_1/s \\
V_2(0,s) &= E_2/s \\
V_2(l,s) &= 0 \\
V_1'(0,s) &= 0 \\
V_1'(l,s) &= E_1/s \\
V_2'(0,s) &= E_2/s \\
V_2'(l,s) &= 0
\end{align*}
\]

Writing these conditions using (5) yields

\[
\begin{align*}
\gamma_1 Y_1 - B Y_1 + n C Y_1 - n D Y_1 &= 0 \\
A e^{\tau d} + B c^{rt} + n C e^{rt} + n D e^{-rt} &= E_1/s \\
A + B - C - D &= E_2/s \\
A Y_1 e^{rt} - B Y_1 e^{-rt} - C Y_1 e^{rt} + D Y_1 e^{-rt} &= 0
\end{align*}
\]

The above linear equations can be solved in terms of \( A, B, C \) and \( D \). Then, the particular solutions for \( V_1(x,s) \) and \( V_2(x,s) \) are obtained.

A. Crosstalk Noise

Although the derived expression for \( V_1(x,s) \) is very complicated, the peak noise amplitude, \( v_{pl} \), can be calculated using the following initial value theorem of Laplace transform. In order to obtain the cross talk noise on \( V_1(x,s) \), \( E_1 \) is set to 0 and \( E_2 \) is set to 0.

\[
v_{pl} = \frac{v_1(x,0)}{E_2} = \lim_{s \to 0} s V_1(0,s)
\]

The resultant expression for the peak noise amplitude is simple as follows. The formulas are exact. Special case expressions for two-, three- and infinite-line systems are also shown.

\[
\begin{align*}
\frac{v_{pl}}{E} &= \frac{n \sqrt{1 + (n + 1) n} - n}{n \sqrt{1 + (n + 1) n} + 1} \quad \text{(general, exact)} \\
\frac{v_{pl}}{E} &= \frac{\sqrt{1 + 2 C_1 / C - 1}}{\sqrt{1 + 2 C_1 / C + 1}} \quad \text{(two - line)} \\
\frac{v_{pl}}{E} &= \frac{2 \sqrt{1 + 3 C_1 / C - 2}}{2 \sqrt{1 + 3 C_1 / C + 1}} \quad \text{(three - line)} \\
\frac{v_{pl}}{E} &= \frac{\sqrt{1 + 4 C_1 / C - 1}}{\sqrt{1 + 4 C_1 / C + 1}} \quad \text{(inf line)}
\end{align*}
\]

If the coupling capacitance \( C_t \) is equal to the ground capacitance \( C \), which can happened in deep submicron designs, \( v_{pl}/E \) for two-, three- and infinite-line systems are 0.27, 0.40 and 0.38, respectively. This means that the noise induced by the coupling would go up to 40% of the signal swing, which may in turn cause malfunction and timing
problems. This situation can be verified by SPICE [4] simulation results as seen in Fig. 6. The SPICE simulation is carried out by using 10 sections of lumped RC blocks.

![Normalized voltage: v/E](image)

**Fig. 6** SPICE simulation results for the case where adjacent lines are driven from the opposite direction (three-line system).

**B. Delay and Slope**

Although the expressions for voltage waveform, $V_1(x,s)$ and $V_2(x,s)$ are also complicated, the moments $m_0$ and $m_1$ of $V_1(0,s)$ can be expressed as below. Once $m_0$ and $m_1$ are obtained, the delay $t_{pd}$ and the slope are calculated using (6).

\[
\begin{align*}
    m_0 &= \frac{1}{RC} E_1 = \frac{1}{2} E_1 \left(1 + mn\right) - E_1 mn \\
    m_1 &= \frac{1}{RC^2} \left(5 + 5n^2\eta^2 + n\eta(10 + 3\eta)\right)
\end{align*}
\]

(8)

The worst case in terms of delay occurs when $n=2$ and the adjacent lines are driven in out-phase fashion, that is, $E_1=1$ and $E_2=-1$. $t_{pd}$ in this worst case is expressed as follows.

\[
t_{pd} = \frac{1}{2} + 2\eta - \frac{1}{\sqrt{6}} \log \frac{e}{2} \sqrt{1 + 6\eta + 2\eta^2} \\
= 1.7\eta + 0.37 \quad (\eta \leq 2)
\]

(9)

Typical delay simulation example is shown in Fig. 7.

![Normalized time: t/RC](image)

**Fig. 7** Delay simulation example for the opposite drive case (three-line system).

5. Same Direction Drive

In this section, the mode where adjacent lines are driven from the same direction is treated. The situation is depicted in Fig. 8. For this case, the equivalent resistance of driver MOSFET $R_t$ and the equivalent capacitance of receiver MOSFET $C_t$ can be taken into account in the analysis, that is, $R_t$ and $C_t$ can be finite.

![Normalized voltage: v/E](image)

**Fig. 8** Adjacent lines are driven from the same direction.

The boundary conditions for this case are written as follows.

\[
\begin{align*}
    -\frac{1}{r} \frac{\partial V_1}{\partial x} |_{x=0} &= \frac{E_1 - V_1}{R_t} \\
    -\frac{1}{r} \frac{\partial V_2}{\partial x} |_{x=0} &= \frac{E_2 - V_2}{R_t} \\
    -\frac{1}{r} \frac{\partial V_2}{\partial x} |_{x=1} &= nC_t \frac{\partial V_2}{\partial t} |_{x=1}
\end{align*}
\]

(10)

**A. Crosstalk Noise**

In order to obtain the crosstalk noise, the moment matching approach is not effective and a special analytical treatment like below is employed. For noise calculation, $E_i$ is set to 0 and $E_3$ is set to $E$.

If we define $u_1 = v_1 + nv_2$ and $u_2 = v_1 - v_2$, $u_1$ and $u_2$ give the following equations.

\[
\begin{align*}
    \frac{\partial^2 u_1}{\partial x^2} &= r_c \frac{\partial u_1}{\partial t} \\
    \frac{\partial^2 u_2}{\partial x^2} &= r_c \frac{\partial u_2}{\partial t} = r_c \frac{\partial u_2}{\partial t} = r_c \frac{\partial u_2}{\partial t}
\end{align*}
\]

(11)

The boundary conditions for $u_1$ and $u_2$ are obtained by linearly combining (10) as follows.

\[
\begin{align*}
    -\frac{1}{r} \frac{\partial u_1}{\partial x} |_{x=0} &= \frac{nE - u_1}{R_t} |_{x=0} \\
    -\frac{1}{r} \frac{\partial u_1}{\partial x} |_{x=1} &= \frac{C_t \partial u_1}{\partial t} |_{x=1} \\
    -\frac{1}{r} \frac{\partial u_2}{\partial x} |_{x=0} &= \frac{E - u_2}{R_t} |_{x=0} \\
    -\frac{1}{r} \frac{\partial u_2}{\partial x} |_{x=1} &= \frac{C_t \partial u_2}{\partial t} |_{x=1}
\end{align*}
\]

(12)
On the other hand, it is well-known that the equation
\[
\frac{\partial^2 v}{\partial x^2} = r_c \frac{\partial v}{\partial t}
\]
with the boundary condition,
\[
\begin{align*}
- \frac{1}{r_c} \frac{\partial v}{\partial x} & \bigg|_{x=0} = \frac{E - v}{R_t}, \\
- \frac{1}{r_c} \frac{\partial v}{\partial x} & \bigg|_{x=1} = C_1 \frac{\partial v}{\partial t}.
\end{align*}
\]
has the following solution [5-7].
\[
\frac{v(l,t)}{E} = 1 + \sum_{n=1}^{\infty} K_n e^{\pm \eta_n t} = 1 + K_1 e^{-\eta_1 t}.
\]
This means that \(v(l,t)\) can be approximated with a single exponential function, \(\sigma_i\) is the pole with minimum absolute value, and \(K_1\) is the corresponding residue and can be approximated as follows.
\[
K_1 = -1.01 \frac{R_t + C_T + 1}{R_T + C_T + \pi/4} R_T + C_T + \pi/4,
\]
\[
\sigma_1 = 1.04 \left( R_T C_T + R_T + C_T + (2/\pi)^2 \right).\]
Comparing the above solved system and (11) and (12), we get approximate formulas for \(u_1\) and \(u_2\). \(v_1\) and \(v_2\) are obtained by a linear combination of \(u_1\) and \(u_2\) as follows.
\[
\frac{v_1(l,t)}{E} = \frac{v_1(0,t)}{E} = \frac{n}{n+1} \left( K_1 e^{-\sigma_1 t} - K_1' e^{-\sigma_1' t} \right),
\]
\[
\frac{v_2(l,t)}{E} = \frac{v_2(0,t)}{E} = 1 + \frac{1}{n+1} \left( K_1 e^{-\sigma_1 t} + nK_1' e^{-\sigma_1' t} \right).
\]
In the above expression, \(K_1'\) and \(\sigma_1'\) are expressed as follows.
\[
K_1' = -1.01 \frac{R_t + C_T + p + 1}{R_T + C_T + p + \pi/4},
\]
\[
\sigma_1' = 1.04 \left( R_T C_T + R_T + C_T + p + (2/\pi)^2 \right).
\]
The peak noise amplitude can be derived by searching for the peak value in (13). This can be achieved by differentiating (13) and solve \(\partial v/\partial t = 0\) in terms of \(t\). If we write the solution to this equation as \(t_{pl}\), \(t_{pl}\) can be expressed as follows.
\[
t_{pl} = \frac{p \ln \frac{K_{10} e^{-\sigma_1 t}}{K_{10} e^{-\sigma_1' t}}}{p \sigma_1 - \sigma_1'}.
\]
Now, putting \(t_{pl}\) back in (13), the peak noise amplitude is obtained.
\[
\frac{v_{pl}}{E} = \frac{v_{0}}{E} \left[ K_1 \left( \frac{\sigma_1}{\sigma_1'} - \frac{\sigma_1}{\sigma_1'} \right) - K_1' \left( \frac{\sigma_1'}{\sigma_1'} - \frac{\sigma_1'}{\sigma_1'} \right) \right].
\]
Several special cases are discussed in the following chapters.

A-1. Noise for the Case: \(R_T, C_T \gg 1\)
In this case, \(K_1 = \sigma_1 = 1\), \(\sigma_1' = 1/(R_T C_T)\) and \(\sigma_1 = p(R_T C_T)\) hold. Then, from (14), \(v_{pl} \rightarrow 0\). This case corresponds to the old situation where interconnection capacitance and resistance are not large compared to MOSFET related resistance and capacitance. For this case, as a matter of course, noise issues can be neglected. The capacitance coupling noise is rather a new headache in VLSI designs.

A-2. Noise for the Case: \(R_T, C_T \ll 1\)
In this case, \(K_1 = \sigma_1 = 1\) and \(\sigma_1' = \pi^2/4\) hold.
\[
\frac{v_{pl}}{E} = \frac{4}{\pi^2} \frac{1}{1 + n\eta} \frac{n\eta}{2 + (n+1)\eta} \quad (valid \ when \ \eta \leq 2)
\]
Special case expressions for two-, three- and infinite-line systems are shown below.
\[
\begin{align*}
\frac{v_{pl}}{E} &= \frac{nC_c}{C} \quad (general) \\
\frac{v_{pl}}{E} &= \frac{nC_c}{C} \quad (two \ - line) \\
\frac{v_{pl}}{E} &= \frac{2nC_c}{C} \quad (three \ - line) \\
\frac{v_{pl}}{E} &= \frac{nC_c}{C} \quad (inf \ - line)
\end{align*}
\]
The approximation is valid when \(C_c \leq 2\). If the coupling capacitance \(C_c\) is equal to the grounding capacitance \(C\) which can happen in deep submicron designs, \(v_{pl}/E\) for two-, three- and infinite-line systems are 0.25, 0.40 and 0.33, respectively. This means that the noise induced by the coupling would go up to 40% of the signal swing, which is the same situation as in the previous section. This situation can be verified by the SPICE simulation as seen in Fig. 9.

Fig. 9 SPICE simulation results for the case where adjacent lines are driven from the same direction (three-line system).
For this case, the time when the noise shows the peak \( t_{pl} \) is approximated as follows.

\[
\frac{t_{pl}}{RC} = \frac{4}{\pi} \frac{p \ln p}{p - 1}
\]

A. Noise for the Case: \( C_T = 1 \)

This is similar to the previous case and the noise amplitude is approximated as follows.

\[
v_{pl} = \frac{R_T + 1}{R_T + 2} \left( \frac{1}{1 + n \eta} \right)^{\frac{1}{n \eta}} \frac{\eta}{1 + n \eta} \\
= \frac{R_T + 1}{1.27R_T + 1 + 2(n+1)\eta} \quad \text{(valid when } \eta \leq 2)\]

A.4. Noise for the Case: \( R_T = 1 \)

In this case,

\[
v_{pl} = \eta \left( \frac{1}{1 + n \eta'} \right)^{\frac{1}{n \eta'}} \frac{\eta'}{1 + n \eta'} \\
= 0.80 \frac{n \eta'}{2 + (n+1)\eta} \quad \text{(valid when } \eta' \leq 2)
\]

, where \( \eta = C_C/(C+C_T) \).

B. Delay and Slope

Although the expressions for voltage waveform are complicated, the moments, \( m_0 \) and \( m_1 \) of \( V_1(l,s) \) can be expressed as below. Once \( m_0 \) and \( m_1 \) are obtained, the delay \( t_{pd} \) and the slope are calculated using (6).

\[
\begin{align*}
m_0 / RC &= \frac{1}{2} \left[ E_1 \left( 2C_T(1 + R_T) + (1 + 2R_T)(1 + n\eta) \right) \\
& \quad -E_2 n\eta(1 + 2R_T) \right] \\
m_1 / (RC)^2 &= \frac{1}{4!} \left[ E_1 \left( 24C_T^2(1 + R_T)^2 \\
& \quad + 4C_T(5 + 15R_T + 12R_T^2)(1 + n\eta) \\
& \quad + (5 + 20R_T + 24R_T^2)(1 + 2n\eta + n^2\eta^2 + n^3\eta^3) \right) \\
& \quad - E_2 n\eta \left( 2(3 + n)(1 + 3R_T) + 6(1 + n)nR_T^2 \right) \\
& \quad + (5 + 20R_T + 24R_T^2)(2 + n + n^2) \right] 
\end{align*}
\]

The worst case in terms of delay occurs when \( n = 2 \) and the adjacent lines are driven in out-phase fashion, that it, \( E_1 = 1 \) and \( E_2 = -1 \). A simple case when \( C_T = R_T = 0 \), \( t_{pd} \) in this worst case is expressed as follows.

\[
\frac{t_{pd}}{RC} = \frac{1}{2} \left[ 2 + 2\eta - \frac{1}{\sqrt{6}} \log \frac{e}{2} \left( 1 + 8\eta + 6\eta^2 \right) \right] \\
= 1.63\eta + 0.37 \quad (\eta \leq 2)
\]

Typical delay simulation example is shown in Fig. 10. It is seen from the figure that \( t_{pd} \) in three-line system varies from 0.37RC (in-phase) to 2.0RC (out-phase) depending on the behavior of the adjacent lines. When \( E_2 = 0 \), \( t_{pd} \) is 0.98RC.
B. Delay and Slope

The simulation results for delay and slope are compared with the calculated results using the analytical formulas (6), (8) and (16) in Fig. 14 through Fig. 21. As seen from the figures, good agreement is observed between the simulated and the calculated results.
7. Approximation with Lumped Circuit

In circuit simulation, π-ladder lumped circuit is often adopted to approximate the distributed RC lines. The error in simulating delay of the distributed RC line by using N-step lumped ladder blocks (Fig. 22) is investigated.

The results are shown in TABLE 1 through TABLE 6. Numbers in the tables signify % error of the delay. The reference (exact delay) is taken from the simulation results with N=10. C_T and R_T are set equal to 0, because this condition corresponds to the worst case in terms of error. When C_T and R_T are finite, they tend to determine the timing behavior of the system and they are lumped circuit elements from first.
It is seen from these tables that 3-step \( \pi \)-ladder network is a good approximation in estimating delay within 4% relative error even in the worst cases.

8. Conclusion

Simple yet useful analytical expressions for peak noise amplitude, delay and slope for capacitively coupled two-, three- and infinite-line systems.

The calculated results using the derived formulas of (7), (14) for the crosstalk noise and (6), (8), (16) for the delay and the slope coincide excellently with SPICE simulation results. The derived approximate expressions like (9), (15) and (17) are useful in estimating the crosstalk noise and delay in the early stage of designs and give insight to coupling related issues.

In deep submicron VLSI designs where \( C_C \) can be comparable to \( C \), the crosstalk induced by the coupling goes up to 40% of the signal swing and the delay fluctuates 5 times depending on the behavior of the adjacent lines.

As for the approximation with lumped circuit, 3-step \( \pi \)-ladder network is good approximation within 4% relative error even in the worst cases.
